

MEE5114 Advanced Control for Robotics

Lecture 11: **Basics** of Optimization

Prof. Wei Zhang

SUSTech Institute of Robotics

Department of Mechanical and Energy Engineering

Southern University of Science and Technology, Shenzhen, China

Outline

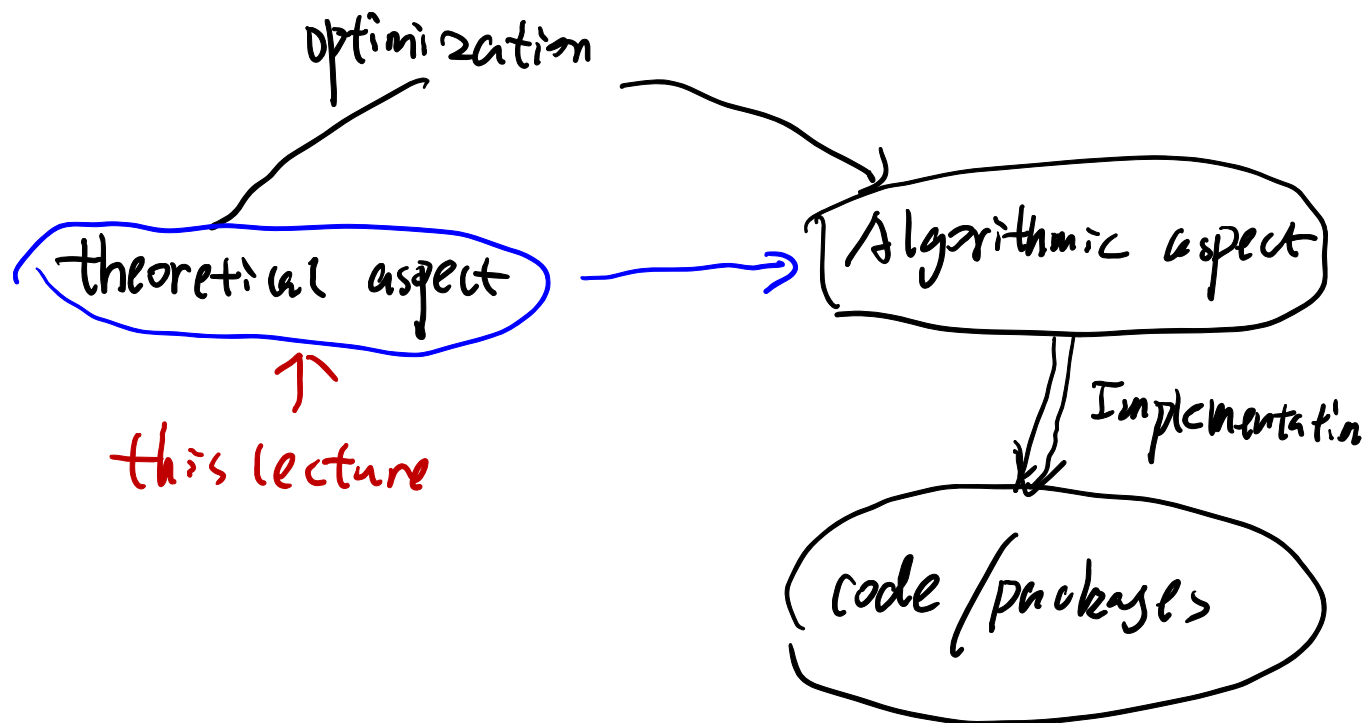

- Motivation
- Some Linear Algebra
- Sets and Functions
- Short Introduction to Optimization
- Linear Program
- Quadratic Program

Motivation

- Optimization is arguably the most important tool for modern engineering
- Robotics
 - ② Differential Inverse Kinematics ←
 - Dynamics : $ABA \Leftrightarrow LQR$
 - Motion planning
 - ④ - Whole-body control: formulated as a quadratic program
 - 'SLAM:'
 - Perception
- Machine Learning
 - Linear regression
 - Support vector machine:
 - Deep learning minimize "loss" func.
- other domains
 - ① - Check system stability: "SDP"
 - Compressive sensing
 - Fourier transform: least square problem
- Roughly speaking, most engineering problems (finding a better design, ensure certain properties of the solution, develop an algorithm), can be formulated as optimization/optimal control problems.

Outline

- Motivation
- Some Linear Algebra
- Sets and Functions
- Short Introduction to Optimization
- Linear Program
- Quadratic Program

Our goal: { Basic knowledge / key concepts of opt. theory
• Formulate / reformulate opt. prob.
• Educated users of tools/packages

Real Symmetric Matrices

- S^n : set of real symmetric matrices in \mathbb{R}^n
 $\cong \mathbb{R}^{n \times n}$ $A \in S^n, \Leftrightarrow A^T = A$

- All eigenvalues are real (diagonalizable)

- There exists a full set of orthogonal eigenvectors

$A \in S^n$ $A = T \Lambda T^{-1}$
 nonsingular matrix
 \downarrow

~~X~~
~~X~~
~~X~~

Spectral decomposition: If $A \in S^n$, then $A = Q \Lambda Q^T$, where Λ diagonal and Q is unitary.

Q is unitary

$Q^T Q = I$ $Q Q^T = I$
 $\Rightarrow Q^T = Q^{-1}$

$Q = [q_1 \mid \dots \mid q_n] \Rightarrow$

q_i is i^{th} -column of Q

$q_i^T q_j = \begin{cases} 1 & \text{if } i=j \\ 0 & \text{otherwise} \end{cases}$ } $\{q_i\}$ orthogonal

Positive Semidefinite Matrices (1/3)

- $A \in \mathcal{S}^n$ is called positive semidefinite (p.s.d.), denoted by $A \succeq 0$, if $x^T A x \geq 0, \forall x \in \mathbb{R}^n$
- $A \in \mathcal{S}^n$ is called positive definite (p.d.), denoted by $A \succ 0$, if $x^T A x > 0$ for all nonzero $x \in \mathbb{R}^n$
- \mathcal{S}_+^n : set of all p.s.d. (symmetric) matrices
- \mathcal{S}_{++}^n : set of all p.d. (symmetric) matrices
- p.s.d. or p.d. matrices can also be defined for non-symmetric matrices.

e.g. $\begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix}$

$$x^T \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} x = x_1^2 + x_2^2$$

- We assume p.s.d. and p.d. are symmetric (unless otherwise noted)
- Notation: $A \succeq B$ (resp. $A \succ B$) means $A - B \in \mathcal{S}_+^n$ (resp. $A - B \in \mathcal{S}_{++}^n$)
 defined a "partial order" on \mathcal{S}^n . $A - B$ p.s.d. it's possible to have $A \not\preceq B$ $A \not\succeq B$

Positive Semidefinite Matrices (2/3)

- Other equivalent definitions for symmetric p.s.d. matrices:

- All $2^n - 1$ principal minors of A are nonnegative

- All eigs of A are nonnegative

- There exists a factorization $A = B^T B$

- Other equivalent definitions for p.d. matrices:

- All n leading principal minors of A are positive

- All eigs of A are strictly positive

- There exists a factorization $A = B^T B$ with B square and nonsingular.

• If $A > 0$, \Rightarrow $A = Q \Lambda Q^T = Q \Lambda^{\frac{1}{2}} \Lambda^{\frac{1}{2}} Q^T = B^T B$

\downarrow eigenvalues > 0 $B = \Lambda^{\frac{1}{2}} Q^T$

$$\Lambda = \begin{bmatrix} 2 & 0 \\ 0 & 4 \end{bmatrix} = \begin{bmatrix} \sqrt{2} & 0 \\ 0 & 2 \end{bmatrix} \begin{bmatrix} \sqrt{2} & 0 \\ 0 & 2 \end{bmatrix}$$

Positive Semidefinite Matrices (3/3)

• Useful facts: p.d.

- If T nonsingular, $A \succ 0$ \Leftrightarrow $T^T A T \succ 0$; and $A \succeq 0$ \Leftrightarrow $T^T A T \succeq 0$

doesn't need to
unitary

Recall: $\left\{ \begin{array}{l} T A T^{-1} : \text{similarity transformation} \\ T^T A T : \text{congruent transformation} \end{array} \right\}$ $\rightarrow \left. \begin{array}{l} S_+^n \\ S_{tr}^n \end{array} \right\}$

are invariant
under congruent
transformation

- Inner product on $\mathbb{R}^{m \times n}$: $\langle A, B \rangle \triangleq \text{tr}(A^T B) \triangleq A \bullet B$

$\forall A \in \mathbb{R}^{m \times n}, B \in \mathbb{R}^{m \times n}$ $\text{tr}(A^T B) = \sum_{i=1}^m \sum_{j=1}^n A_{ij} B_{ij}$

Angle between A, B $\cos \theta = \frac{\langle A, B \rangle}{\sqrt{\langle A, A \rangle \langle B, B \rangle}}$

- For $(A, B \in S_+^n)$ $\text{tr}(AB) \geq 0$

A, B square, symmetric, p.s.d.

$\left\{ \begin{array}{l} A \perp B \Rightarrow \text{tr}(A^T B) = 0 \\ \text{tr}(A^T B) > 0 \Rightarrow \text{acute} \end{array} \right.$

$\langle A, B \rangle = \text{tr}(A^T B) = \text{tr}(AB) \xrightarrow{\text{Fact}} \text{tr}(AB) \geq 0$
↓
HW

Positive Semidefinite Matrices (4/1)

- For any symmetric $A \in \mathcal{S}^n$,

$$\underbrace{\lambda_{\min}(A) \geq \mu}_{\text{wavy line}} \Leftrightarrow \underbrace{A \succeq \mu I}_{\text{bracket}} \quad \text{and} \quad \underbrace{\lambda_{\max}(A) \leq \beta \Leftrightarrow A \preceq \beta I}_{\text{wavy line}}$$

proof: $A \in \mathcal{S}^n$

$$A - \mu I \succeq 0$$

$\Rightarrow A = Q\Lambda Q^T$, for unitary Q .

$$\underbrace{A - \mu I}_{\text{bracket}} = Q(\Lambda - \mu I)Q^T$$

$$A - \mu I \succeq 0 \Leftrightarrow \underbrace{\Lambda - \mu I}_{\text{bracket}} \succeq 0$$

$$\Leftrightarrow \begin{bmatrix} \lambda_1 & & 0 \\ & \lambda_2 & \\ 0 & & \lambda_n \end{bmatrix} - \begin{bmatrix} \mu & & \\ & \mu & \\ & & \mu \end{bmatrix} \succeq 0$$

$$\Leftrightarrow \lambda_{\min}(A) \geq \mu$$

Outline

- Motivation
- Some Linear Algebra
- **Sets and Functions**
- Short Introduction to Optimization
- Linear Program
- Quadratic Program

Affine Sets and Functions (1/3)

constant $f(x) = c$

- Linear mapping: $f(x + y) = f(x) + f(y)$ and $f(\alpha x) = \alpha f(x)$, for any x, y in some vector space, and $\alpha \in \mathbb{R}$

Examples

- $f(x) = Ax, x \in \mathbb{R}^3, A \in SO(3)$ ← check definitions

$$f(x+y) = A(x+y) = Ax + Ay = f(x) + f(y),$$

- $f[x] = \int x(\tau) d\tau$, for all integrable function $x(\cdot)$

integrable function of τ

$$f[x+y] = \int (x(\tau) + y(\tau)) d\tau = \int x(\tau) d\tau + \int y(\tau) d\tau$$

- $E(x)$ expectation of a random variable/vector x $= f(x) + f(y)$

$$E(x) = \int x f(x) dx$$

- $f(x) = \text{tr}(x), x \in R^{n \times n}$

$$\text{tr}(A+B) = \text{tr}(A) + \text{tr}(B)$$

$$\text{tr}(\alpha A) = \alpha \text{tr}(A)$$

$$\min_x \text{tr}(x) \leftarrow \text{l.p.}$$

Affine Sets and Functions (2/3)

- Affine mapping: $\underline{f(x)}$ is an affine mapping of x if $\underline{g(x)} \triangleq \underbrace{f(x) - f(x_0)}$ is a linear mapping for some fixed x_0

- Finite-dimension representation of affine function: $\underline{f(x) = Ax + b}$

$$g(x) = A f(x) - f(0) = Ax + b - b = Ax$$

- Homogeneous representation in \mathbb{R}^n :

$$\underline{f(x) = Ax + b} \Leftrightarrow \underbrace{\tilde{f}(\tilde{x}) = \tilde{A}\tilde{x}}_{\text{circled}}$$

with $\tilde{A} = \begin{bmatrix} A & b \\ 0 & 1 \end{bmatrix}, \tilde{x} = \begin{bmatrix} x \\ 1 \end{bmatrix}$

- Linear and affine are often used interchangeably

Affine Sets and Functions (3/1)

- Linear/affine sets: $\{x : f(x) \leq 0\}$ for affine mapping f
 \nwarrow sublevel set

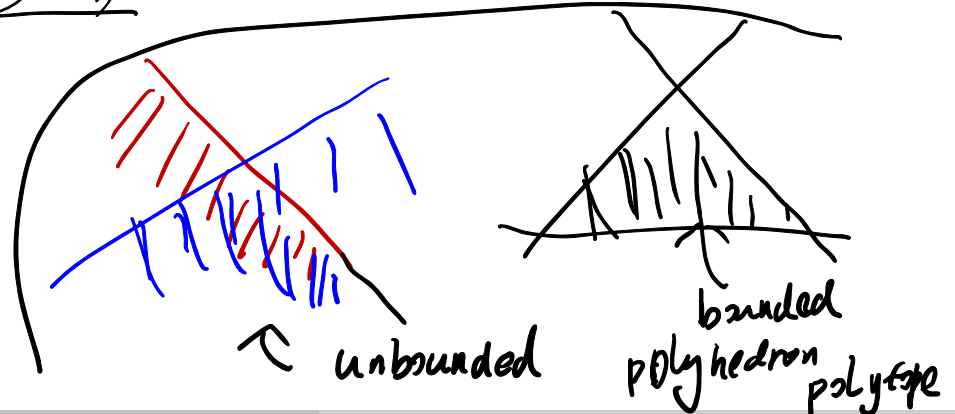

- Line/hyperplane: $a^T x = b \Rightarrow a^T x - b = 0$
 $\Rightarrow a^T (x - x_0) = 0 \Rightarrow a^T x - a^T x_0 = 0$

- Half space: $a^T x \leq b$
 $a^T x - a^T x_0 \leq 0 \Leftrightarrow \langle a, x - x_0 \rangle \leq 0$

- Polyhedron: $Hx \leq h$ $\rightarrow \in \mathbb{R}^m$
 $H \in \mathbb{R}^{m \times n}$ $x \in \mathbb{R}^n$
 $H = \begin{bmatrix} H_1^T \\ H_2^T \\ \vdots \\ H_m^T \end{bmatrix} \cdot x \leq \begin{bmatrix} h_1 \\ h_2 \\ \vdots \\ h_m \end{bmatrix} \Rightarrow$ Imposes m inequalities
 $H_i^T x \leq h_i$
 Half space

- For matrix variable $X \in \mathbb{R}^{n \times n}$ $\text{tr}(AX) \leq 0$ for given constant matrix $A \in \mathbb{R}^{n \times n}$ is a halfspace in $\mathbb{R}^{n \times n}$

Quadratic Sets and Functions $f(x) = f(x_1, x_2) = x_1^2 + 3x_1x_2 + x_2^2$

- Quadratic functions in \mathbb{R}^n : $f(x) = x^T A x + b^T x + c$ $\tilde{x} = \begin{bmatrix} x \\ 1 \end{bmatrix} \in \mathbb{R}^{n+1}$
 $x = \begin{bmatrix} x_1 \\ \vdots \\ x_n \end{bmatrix}, f: \mathbb{R}^n \rightarrow \mathbb{R}$
- Quadratic functions (homogeneous form): $f(x) = x^T A x$
 $f(x) = \underbrace{\begin{bmatrix} x \\ 1 \end{bmatrix}}_{\tilde{x}^T} \underbrace{\begin{bmatrix} A & \frac{1}{2}b \\ \frac{1}{2}b^T & c \end{bmatrix}}_{\tilde{A}} \underbrace{\begin{bmatrix} x \\ 1 \end{bmatrix}}_{\tilde{x}}$

- $A \in S_+^n \Leftrightarrow f(x) \geq 0, \forall x \in \mathbb{R}^n$ f : P.S.D.
 $f(x) > 0$, for all $x \neq 0$
 $f(x) = 0$ for $x = 0$

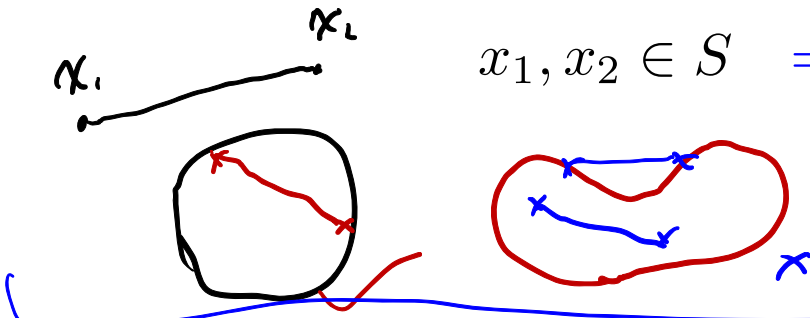

- Quadratic sets: $\{x \in \mathbb{R}^n : f(x) \leq 0\}$ for some quadratic function f

- e.g.: Ball: \mathbb{R}^n . $\{x \in \mathbb{R}^n : \|x - x_c\|^2 \leq r_c^2\}$
 \downarrow
 $f(x) = (x - x_c)^T (x - x_c) - r_c^2 \leq 0$
- e.g.: Ellipsoid:
 $\{x \in \mathbb{R}^n : (x - x_c)^T P^{-1} (x - x_c) \leq 1\}$
 $P \in S_{++}^n$

e.g.: $\{x \in \mathbb{R}^2 : x_1, x_2 = 1\}$
 $x_1^2 \leq 2$

Convex Set

- **Convex Set:** A set S is convex if any line segment stays in the set.

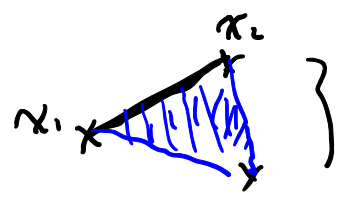

$x_1, x_2 \in S \Rightarrow \underline{\alpha x_1 + (1 - \alpha)x_2} \in S, \forall \alpha \in [0, 1]$
 $= \alpha_1 x_1 + \alpha_2 x_2, \begin{cases} \alpha_1 + \alpha_2 = 1 \\ \alpha_1, \alpha_2 \geq 0 \end{cases}$

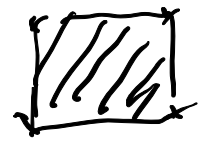

convex combination of x_1, x_2

- **Convex combination of x_1, \dots, x_k :**

$$\left(\alpha_1 x_1 + \alpha_2 x_2 + \dots + \alpha_k x_k : \alpha_i \geq 0, \text{ and } \sum_i \alpha_i = 1 \right)$$

3 pts. $\alpha_1 x_1 + \alpha_2 x_2 + \alpha_3 x_3$

- **Convex hull:** $\overline{\text{co}}\{S\}$ set of all convex combinations of points in S

Cone

- A set S is called a cone if $\lambda > 0, x \in S \Rightarrow \lambda x \in S$.

not convex
is a cone

- Conic combination of x_1 and x_2 :
 $x = \alpha_1 x_1 + \alpha_2 x_2$ with $\alpha_1, \alpha_2 \geq 0$

$$\text{cone}(x_1, \dots, x_k) = \{ \sum \alpha_i x_i : \alpha_i \geq 0 \}$$

- *Convex cone*:

1. a cone that is convex

2. equivalently, a set that contains all the conic combinations of points in the set

Positive Semidefinite Cone

Define $S_+^n = S_+^n$

- The set of positive semidefinite matrices (i.e. S_+^n) is a convex cone and is referred to as the *positive semidefinite (PSD) cone*

S_+^n : set of P.S.D. : pick $A \in S_+^n \Rightarrow \lambda A \succeq 0 \Rightarrow \lambda A \in S_+^n$ ($\lambda \geq 0$)

S_+^n is cone.

By definition:

pick arbitrary $A, B \in S_+^n$, $\alpha A + (1-\alpha)B \in S_+^n$ ($\alpha \in [0, 1]$)

By definition of P.S.D., $x^T(\alpha A + (1-\alpha)B)x = \alpha(x^T A x) + (1-\alpha)(x^T B x) \geq 0$

- Recall that if $A, B \in S_+^n$, then $tr(AB) \geq 0$. This indicates that the cone S_+^n is acute.

$x_1 \in \mathbb{R}^n, x_2 \in \mathbb{R}^n$

$\begin{cases} \alpha_1 A + \alpha_2 B \\ \alpha_1 + \alpha_2 = 1 \end{cases}$

Q.E.D.

- $\alpha_1 x_1 + \alpha_2 x_2$, linear combination

- $d_1 x_1 + d_2 x_2$, $d_1 \geq 0, d_2 \geq 0$, conic combination

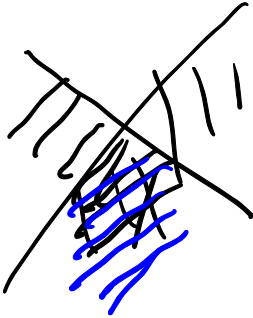

- $\alpha_1 x_1 + \alpha_2 x_2$, $\alpha_i \geq 0, \sum \alpha_i = 1$ convex combination

Operations that Preserve Convexity (1/1)

- Intersection of possibly infinite number of convex sets: is convex

- e.g.: polyhedron: $H_1^T x \leq h_1 \quad H_2^T x \leq h_2$

$\begin{bmatrix} H_1^T \\ H_2^T \end{bmatrix} x \leq \begin{bmatrix} h_1 \\ h_2 \end{bmatrix}$

- e.g.: PSD cone:

- Affine mapping $f : \mathbb{R}^n \rightarrow \mathbb{R}^m$ (i.e. $f(x) = Ax + b$)
 - $f(X) = \{f(x) : x \in X\}$ is convex whenever $X \subset \mathbb{R}^n$ is convex
 - e.g.: Ellipsoid: $E_1 = \{x \in \mathbb{R}^n : (x - x_c)^T P (x - x_c) \leq 1\}$ or equivalently $E_2 = \{x_c + Au : \|u\|_2 \leq 1\}$
 - Ball: $\{x \in \mathbb{R}^n : \|x\|_2 \leq 1\}$
 - Define: $f(x) = P^{-\frac{1}{2}}(x - x_c)$ $E_1 = f(\text{Ball})$
 - $f^{-1}(Y) = \{x \in \mathbb{R}^n : f(x) \in Y\}$ is convex whenever $Y \subseteq \mathbb{R}^m$ is convex
 - e.g.: $\{Ax \leq b\} = f^{-1}(\mathbb{R}_+^n)$, where \mathbb{R}_+^n is nonnegative orthant

$P = P^{-\frac{1}{2}} P^{-\frac{1}{2}}$
 P is P.D.

Convex Function

Consider a finite dimensional vector space \mathcal{X} . Let $\mathcal{D} \subset \mathcal{X}$ be convex.

Definition 1 (Convex Function).

A function $f : \mathcal{D} \rightarrow \mathbb{R}$ is called convex if

$$f(\alpha x_1 + (1 - \alpha)x_2) \leq \alpha f(x_1) + (1 - \alpha)f(x_2), \forall x_1, x_2 \in \mathcal{D}, \forall \alpha \in [0, 1]$$

$\alpha=0$

- $f : \mathcal{D} \rightarrow \mathbb{R}$ is called "strictly" convex if $f(\alpha x_1 + (1 - \alpha)x_2) < \alpha f(x_1) + (1 - \alpha)f(x_2), \forall x_1 \neq x_2 \in \mathcal{D}, \forall \alpha \in [0, 1]$

- $f : \mathcal{D} \rightarrow \mathbb{R}$ is called concave if $-f$ is convex

How to Check a Function is Convex?

- Directly use definition
- First-order condition: If f is differentiable over an open set that contains \mathcal{D} , then f is convex over \mathcal{D} iff

stay above Taylor around x

$$f(z) \geq f(x) + \nabla f(x)^T (z - x), \forall x, z \in \mathcal{D}$$

- Second-order condition: Suppose f is twice differentiable over an open set that contains \mathcal{D} , then f is convex over \mathcal{D} iff

$$\nabla^2 f(x) \succeq 0, \quad \forall x \in \mathcal{D}$$

concave $\nabla^2 f(x) \preceq 0, \forall x \in \mathcal{D}$.

- Many other conditions, tricks,

Examples of Convex Functions

- In general, affine functions are both convex and concave

- e.g.: $f(x) = a^T x + b$, for $x \in \mathbb{R}^n$ $\nabla^2 f(x) = 0$

- e.g.: $f(X) = \text{tr}(A^T X) + c = \sum_{i=1}^m \sum_{j=1}^n A_{ij} X_{ij} + c$, for $X \in \mathbb{R}^{m \times n}$
 $f: \mathbb{R}^{m \times n} \rightarrow \text{scalar}$ / affine func of X (matrix) m x n matrix

- Quadratic functions: $f(x) = x^T Q x + b^T x + c$ is convex iff $Q \succeq 0$

using 2nd-order condition

$$\nabla^2 f(x) = \begin{bmatrix} \frac{\partial^2 f}{\partial x_1 \partial x_1} & \frac{\partial^2 f}{\partial x_1 \partial x_2} & \dots \\ \dots & \dots & \dots \end{bmatrix} = Q$$

n x n matrix

$$x = \begin{bmatrix} x_1 \\ \vdots \\ x_n \end{bmatrix} \in \mathbb{R}^n$$

- All norms are convex

- e.g. in \mathbb{R}^n : $f(x) = \|x\|_p = (\sum_{i=1}^n |x_i|^p)^{1/p}$; $f(x) = \|x\|_\infty = \max_k |x_k|$

- e.g. in $\mathbb{R}^{m \times n}$: $f(X) = \|X\|_2 = \sigma_{\max}(X)$

$$\begin{cases} \|x\|_1 = |x_1| + |x_2| + \dots + |x_n| \\ \|x\|_\infty = \max_k |x_k| \\ \|x\|_2 = \sqrt{x_1^2 + \dots + x_n^2} \end{cases}$$

- Affine mapping of convex func is still convex.

eg. suppose $f(x)$ convex $\Rightarrow g(x) \triangleq af(x) + b$ is also convex

HW#

- Pointwise maximum of convex func is convex

suppose $f_1(x), f_2(x)$ are convex $\Rightarrow g(x) \triangleq \max\{f_1(x), f_2(x)\}$

then g is convex

suppose $f(x; \theta)$ is convex for each $\theta \in [1, 2]$

then $g(x) \triangleq \max_{\theta \in [1, 2]} f(x; \theta)$ convex

eg. $f(x; \theta) = \theta x + b \Rightarrow g(x) = \max_{\theta \in [1, 2]} \theta x + b$

- Pointwise minimum of concave func is concave.

$g(x) = \min_{\theta \in [1, 2]} \theta x + b$ is concave

- Quadratic Program

Nonlinear Optimization Problems

Nonlinear Optimization: primal problem $x = \begin{bmatrix} x_1 \\ \vdots \\ x_n \end{bmatrix} \in \mathbb{R}^n$

minimize: $f_0(x)$ cost func. $f_0: \mathbb{R}^n \rightarrow \mathbb{R}$ constraint set

subject to: $f_i(x) \leq 0, i = 1, \dots, m$
 $h_i(x) = 0, i = 1, \dots, q$
 $x \in \mathcal{D}$

$$\mathcal{C} = \{x \in \mathbb{R}^n : f_i(x) \leq 0, i=1, \dots, m \\ h_i(x) = 0, i=1, \dots, q\}$$

- decision variable $x \in \mathbb{R}^n$, domain \mathcal{D} , referred to as *primal problem*

if $x \in \mathcal{C}$, then
 x is called
 feasible

- optimal value p^*

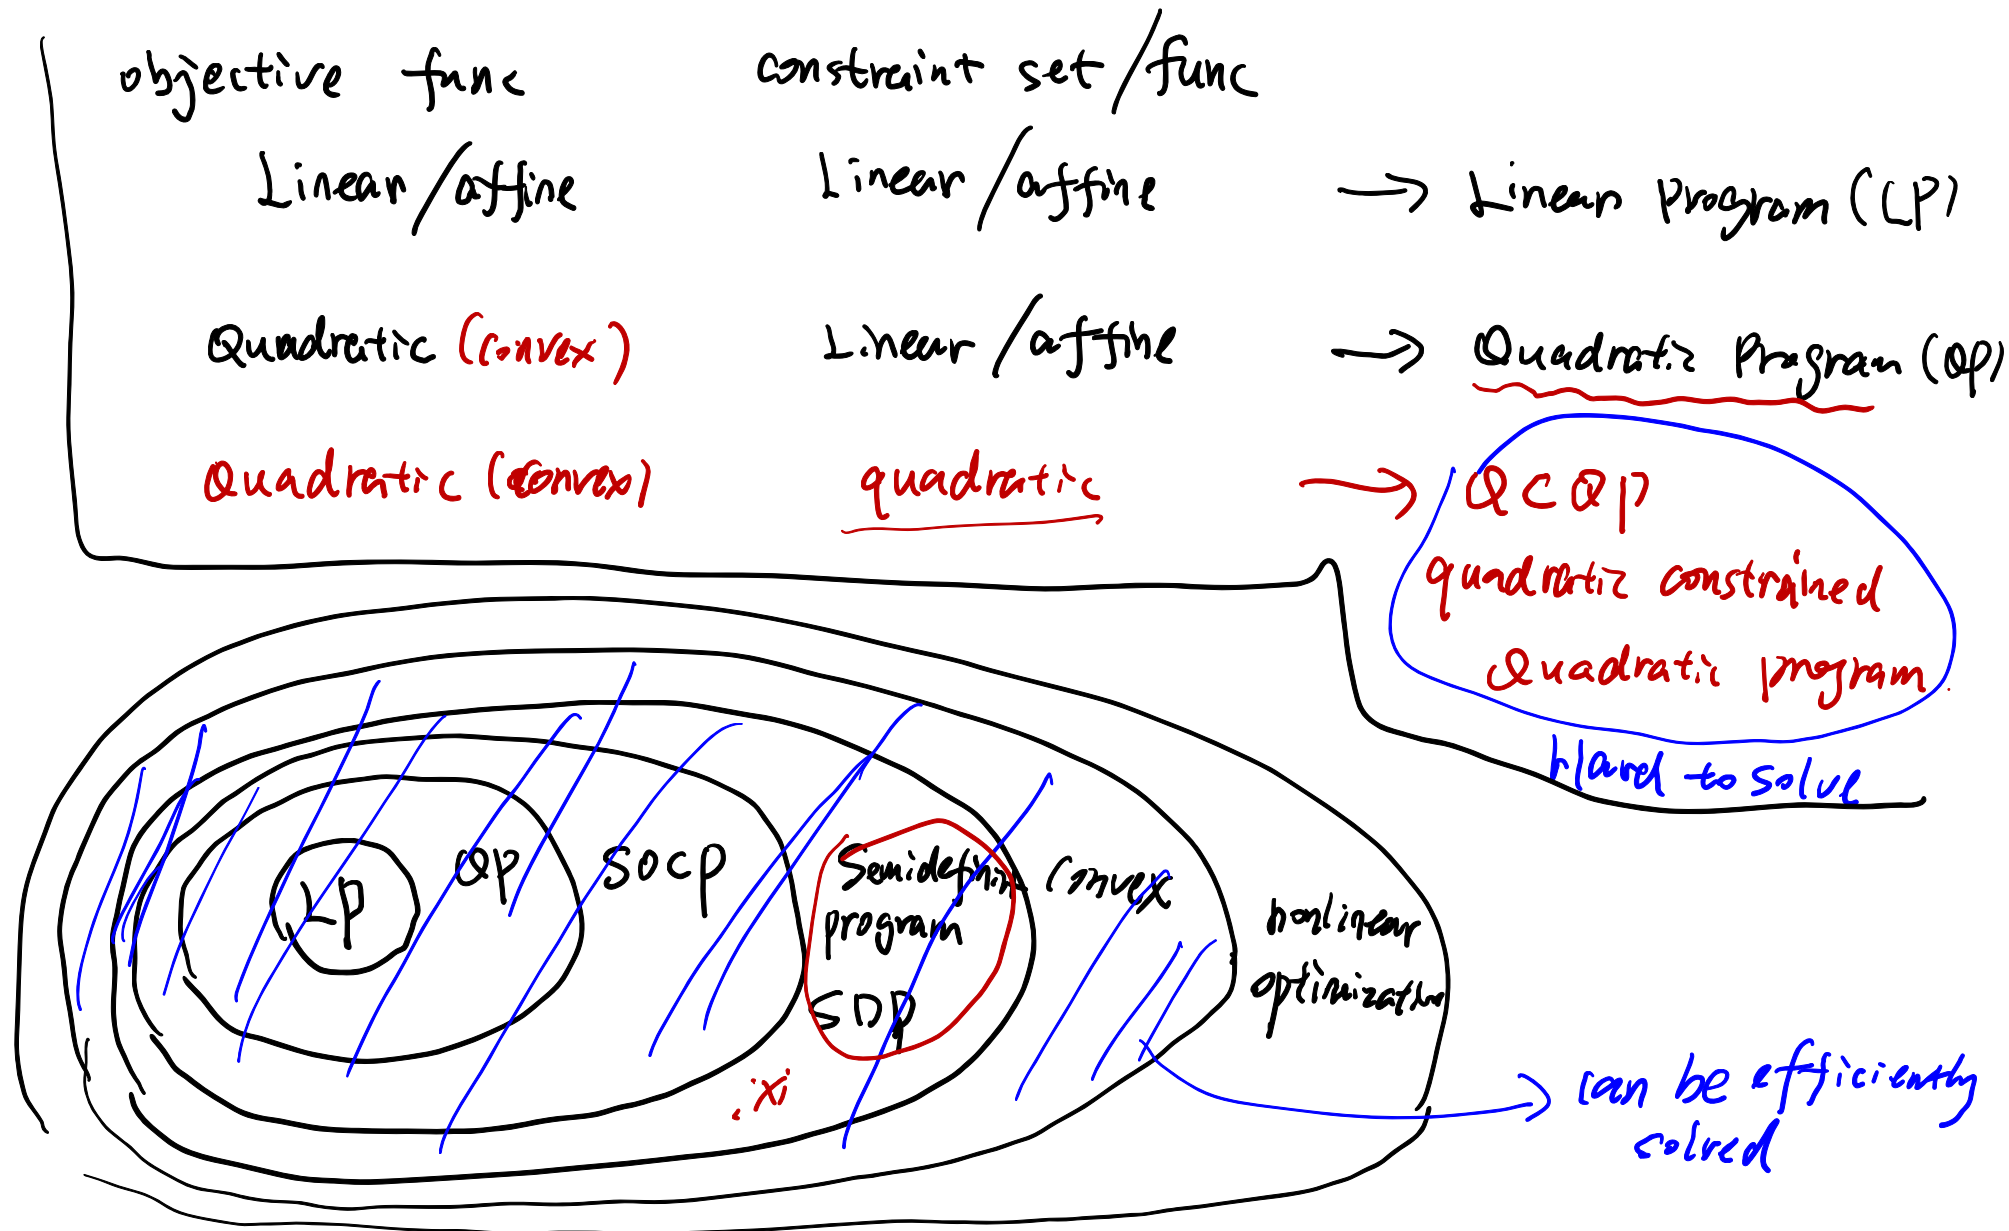

- is called a convex optimization problem if f_0, \dots, f_m are convex and h_1, \dots, h_q are affine

\Rightarrow means: objective func f_0 is convex
 and constraint set is convex

- typically convex optimization can be solved efficiently

Nonlinear Optimization Problems

- Categories:

- How to find optimal soln?

• optimality condition: for unconstrained problems (general)

• 1st-order optimality condition: x^* is local minimizer

then $\nabla f(x^*) = 0$... ① $\begin{bmatrix} \frac{\partial f}{\partial x_1} \\ \vdots \end{bmatrix}$ → suppose $\frac{\partial f}{\partial x_1} > 0$, then $x = \begin{bmatrix} x_1^* - \epsilon \\ \vdots \end{bmatrix}$

Taylor expansion: $f(x) \approx f(x^*) + (\nabla f(x^*))^T (x - x^*) + \text{H.o.T.}$

• For convex problem, condition ① guarantees x^* is global minimizer

Question: what about constrained optimization?

Lagrangian

Associated **Lagrangian**: $L : \mathcal{D} \times \mathbb{R}^m \times \mathbb{R}^q \rightarrow \mathbb{R}$

$$L(x, \lambda, \nu) = \underbrace{f_0(x)}_{\text{objective func}} + \sum_{i=1}^m \lambda_i f_i(x) + \sum_{i=1}^q \nu_i h_i(x),$$

require $\lambda_i \geq 0, \forall i$

- weighted sum of objective and constraints functions
- λ_i : Lagrangian multiplier associated with $\underbrace{f_i(x) \leq 0}$
- ν_i : Lagrangian multiplier associated with $h_i(x) = 0$

Lagrange Dual Problems (1/2)

Lagrange dual function: $g : \mathbb{R}^m \times \mathbb{R}^q \rightarrow \mathbb{R}$

$$g(\lambda, \nu) = \inf_{x \in \mathcal{D}} L(x, \lambda, \nu)$$

is a func of the multipliers

$$= \inf_{x \in \mathcal{D}} f_0(x) + \sum_{i=1}^m \lambda_i f_i(x) + \sum_{i=1}^q \nu_i h_i(x)$$

- ① $L(x, \lambda, \nu)$ is affine in (λ, ν) for each x
- ② pointwise min of affine (concave) is concave

- g is concave, (λ, ν) always true (regardless of whether the primal problem is convex or not) can be $-\infty$ for some λ, ν

- 2° • Lower bound property: If $\lambda \geq 0$ (elementwise), then $g(\lambda, \nu) \leq p^*$

Let \tilde{x} be arbitrary feasible primal variable and $\lambda \geq 0$

$$\Downarrow f_i(\tilde{x}) \leq 0, h_i(\tilde{x}) = 0$$

$$\Rightarrow f_0(\tilde{x}) \geq L(\tilde{x}, \lambda, \nu) \geq \left[\inf_x L(x, \lambda, \nu) \right] = g(\lambda, \nu)$$

$$\Rightarrow \min_{\tilde{x} \text{ feasible}} f_0(\tilde{x}) \geq g(\lambda, \nu)$$

$g^* =$

Lagrange Dual Problems (2/1)

Lagrange Dual Problem:

$$\begin{aligned} & \left(\begin{array}{l} \text{maximize}_{\lambda, \nu} : \frac{g(\lambda, \nu)}{\nu \in \mathbb{R}^2} \\ \text{subject to: } \lambda \geq 0 \end{array} \right) \Leftrightarrow \left(\begin{array}{l} \text{min } (-g(\lambda, \nu)) \\ \text{subj: } -\lambda \leq 0 \end{array} \right) \end{aligned}$$

a large convex optimization problem

- Find the best lower bound on p^* using the Lagrange dual function

dual prob is

- a convex optimization problem even when the primal is nonconvex
- optimal value denoted d^*
- (λ, ν) is called **dual feasible** if $\lambda \geq 0$ and $(\lambda, \nu) \in \mathbf{dom}(g)$
- Often simplified by making the implicit constraint $(\lambda, \nu) \in \mathbf{dom}(g)$ explicit

Duality Theorems

- **Weak Duality:** $d^* \leq p^*$
 - always hold (for convex and nonconvex problems)
 - can be used to find nontrivial lower bounds for difficult problems
- **Strong Duality:** $d^* = p^*$
 - not true in general, but typically holds for convex problems
 - conditions that guarantee strong duality in convex problems are called *constraint qualifications*
 - Slater's constraint qualification: Primal is strictly feasible

$$\text{i.e. } \exists \tilde{x} \text{ such } f_i(\tilde{x}) < 0, \quad h_i(\tilde{x}) = 0$$

General Optimality Conditions (1/3)

For general optimization problem:

$$\begin{aligned} & \text{minimize:} && f_0(x) \\ & \text{subject to:} && f_i(x) \leq 0, i = 1, \dots, m \\ & && h_i(x) = 0, i = 1, \dots, q \end{aligned}$$

General optimality condition:

strong duality and (x^*, λ^*, ν^*) is primal-dual optimal \Leftrightarrow

- $x^* = \arg \min_x L(x, \lambda^*, \nu^*)$ (Lagrange optimality)
- $\lambda_i^* f_i(x^*) = 0$ for all i (Complementarity)
Handwritten notes: ① $\lambda_i = 0, f_i(x^)$ arbitrary; ② $\lambda_i > 0, f_i(x^*) = 0$*
- ✓ • $f_i(x^*) \leq 0, h_j(x^*) = 0$, for all i, j (primal feasibility)
- ✓ • $\lambda_i^* \geq 0$ for all i (dual feasibility)

General Optimality Conditions (2/3)

Proof of Necessity

- Assume x^* and (λ^*, ν^*) are primal-dual optimal slns with zero duality gap,

$$\underbrace{f_0(x^*)}_{p^*} = \underbrace{g(\lambda^*, \nu^*)}_{d^*} = \underbrace{L(x^*, \lambda^*, \nu^*)}_1$$

$$= \min_{x \in \mathcal{D}} f_0(x) + \sum_i \lambda_i^* f_i(x) + \sum_j \nu_j^* h_j(x)$$

$$\min_x L(x, \lambda^*, \nu^*)$$

$$\leq L(x^*, \lambda^*, \nu^*)$$

$$\leq f_0(x^*) + \sum_i \lambda_i^* f_i(x^*) + \sum_j \nu_j^* h_j(x^*)$$

$$\leq f_0(x^*)$$

$$\left. \begin{array}{l} \lambda_i \geq 0, \text{ dual feasible} \\ f_i(x^*) \leq 0, \text{ primal feasible} \end{array} \right\}$$

- Therefore, all inequalities are actually equalities
- Replacing the first inequality with equality $\Rightarrow x^* = \operatorname{argmin}_x L(x, \lambda^*, \nu^*)$
- Replacing the second inequality with equality \Rightarrow complementarity condition

General Optimality Conditions (3/1)

Proof of Sufficiency

- Assume (x^*, λ^*, ν^*) satisfies the optimality conditions:

$$\begin{aligned} d^* &\Leftarrow \underbrace{g(\lambda^*, \nu^*)}_{\min_x L(x, \lambda^*, \nu^*)} = f(x^*) + \sum_i \lambda_i^* f_i(x^*) + \sum_j \nu_j^* h_j(x^*) \\ &= \underbrace{f(x^*)}_{= p^*} = p^* \end{aligned} \quad \begin{array}{l} \nearrow = 0 \text{ (primal} \\ \text{feasible)} \end{array}$$

- The first equality is by Lagrange optimality, and the 2nd equality is due to complementarity
- Therefore, the duality gap is zero, and (x^*, λ^*, ν^*) is the primal dual optimal solution

KKT Conditions

For **convex** optimization problem:

$$\begin{aligned} & \text{minimize:} && f_0(x) \\ & \text{subject to:} && f_i(x) \leq 0, i = 1, \dots, m \\ & && : \quad h_i(x) = 0, i = 1, \dots, q \end{aligned}$$

Suppose duality gap is zero, then (x^*, λ^*, ν^*) is primal-dual optimal if and only if it satisfies the Karush-Kuhn-Tucker (KKT) conditions

- $\frac{\partial L}{\partial x}(x, \lambda^*, \nu^*) = 0$ \Leftarrow *due to primal convexity* (Stationarity)
- $\lambda_i^* f_i(x^*) = 0$ for all i (Complementarity)
- $f_i(x^*) \leq 0$ $h_j(x^*) = 0$, for all i, j (primal feasibility)
- $\lambda_i^* \geq 0$ for all i (dual feasibility)

Linear Program: Primal and Dual Formulations

- Primal Formulation:**

$$\begin{aligned} & \underset{x}{\text{minimize:}} && c^T x \\ & \text{subject to:} && Ax = b \\ & && x \geq 0, \quad x_1 \geq 0, \dots, x_n \geq 0 \end{aligned}$$

n variables
 q - equality constraint
 n - inequalities

$f(x) \leq 0$
 $(-x) \leq 0$

Lagrangian func: $L(x, \lambda, \nu) = c^T x + \lambda^T (-x) + \nu^T (Ax - b)$

$$\Rightarrow g(\lambda, \nu) \triangleq \inf_{x \in \mathbb{R}^n} \{ (c^T - \lambda^T + \nu^T A) x - \nu^T b \}$$

$\min_{x \in \mathbb{R}^n} -2x + 3$

$$= \begin{cases} -\infty & \text{if } c^T - \lambda^T + \nu^T A \neq 0 \\ -b^T \nu & \text{if } c^T - \lambda^T + \nu^T A = 0 \end{cases}$$

$\lambda, \nu \in \text{dom}(g)$

- Its Dual:**

$$\begin{aligned} & \text{maximize:} && -b^T \nu \\ & \text{subject to:} && A^T \nu + c \geq 0 \end{aligned}$$

q - variables
 n - inequality constraint

$$\begin{aligned} & \max_{\lambda, \nu} && g(\lambda, \nu) \\ & \text{subject to:} && \lambda \geq 0 \\ & && c^T - \lambda^T + \nu^T A = 0 \end{aligned}$$

Unconstrained Quadratic Program: Least Squares

- minimize: $J(x) = \frac{1}{2}x^T Qx + q^T x + q_0$
- Problem is convex iff $Q \succeq 0$
- When J is convex, it can be written as: $J(x) = \|Q^{\frac{1}{2}}x - y\|^2 + c$

- KKT condition:

- Optimal solution:

Equality Constrained Quadratic Program

- (
- Standard form:
$$\begin{aligned} \min_x \quad & J(x) = x^T Q x + q^T x + q_0 \\ \text{subject to:} \quad & Hx = h \end{aligned}$$
 - The problem is convex if $Q \succeq 0$
 - KKT Condition:

 - Optimal Solution:

General Quadratic Program

- Standard form:
$$\begin{aligned} & \text{minimize: } J(x) = x^T Qx + q^T x + q_0 \\ & \text{subject to: } Ax \leq b \end{aligned}$$
- Dual problem:
